DETERMINATION OF DESCRIPTORS WHICH INFLUENCE THE TOXICITY OF ORGANOCHLORINE COMPOUNDS USING QSAR METHOD

SUMMARY

Organochlorine Pesticides (OCP) are organic compounds obtained by the chlorination of various unsaturated hydrocarbons. They are very toxic and therefore belong to the family of persistent organic pollutants. If formerly these pesticides were used ~~to improve the productivity and to~~ fight against certain vectors of diseases and thus improve the productivity of the host, today they are considered as "enemy" of the environment. To understand the origin of the toxicity of organochlorine compounds, we used 73 molecules (test set: 50 and validation: 23) containing at least one chlorine atom and for which the toxicity (LogLC_{50}) against *Poecilia reticulata* is known to establish QSAR models. Firstly, we used principal component analysis (PCA) to identify the best descriptors. Then, the different models ~~are were~~ established using the method of multiple linear regression (MLR). Models established with quantum and physicochemical descriptors only showed satisfactory results. But the best model ~~is was~~ determined with the combination of both quantum and physicochemical descriptors. The criteria of this model are as follows:

$$R^2 = 0.939; R_{adjusted}^2 = 0.932; P_{value} < 0.0001; \alpha = 0.05$$

$$R_{CV}^2 = 0.935; R^2 - R_{CV}^2 = 0.004; MCE = 0.073; F = 134.701$$

These criteria show that the toxicity of organochlorine compounds is well described by the combination of quantum and physicochemical descriptors namely lipophilia (LogP), polarizability (pol), entropy (S), zero-point energy (ZPE) and the number of chlorine atoms (NCl).

Key words: organochlorine compounds, toxicity, QSAR, quantum descriptors and physicochemical descriptors

1- INTRODUCTION

Organochlorine pesticides use began in the 1940s with the advent of dichlorodiphenyl- trichloroethane (DDT) which was synthesized for the first time by Othmar Zeidler in 1873 [1] and whose insecticidal properties were discovered by Paul Müller in 1939 [2]. These pesticides have contributed to improved and increased agricultural yields and have led to progress in the control of food resources [3]. The use of organochlorine pesticides has not been limited to increasing agricultural yields, it has also spread to other sectors. Indeed, organochlorine pesticides have long time been used to fight against certain diseases vectors [4-7]. DDT is one of the insecticides recommended by WHO for indoor residual spraying for malaria control [8].

After two decades of intense use, research [7, 9] ~~has~~ begun to show the dangerousness of these chemical compounds to the environment.

Over time, several studies [10-13] ~~will~~ proved their presence in all ecosystems and their effects on elements which live there. The presence of organochlorine pesticides in all ecosystems is assumed to be due to both their persistence their volatility.

Formatted: Subscript

Comment [U1]: Write in full the first time and abbreviate thereafter

40 The persistence of organochlorine compounds in the environment is largely due to the stability of the carbon-
41 chlorine bond that is resistant to degradation. But their presence throughout the food chain is the consequence of
42 their lipo-solubility. This property gives them the ability to cross the phospholipid structure of biological
43 membranes thereby reaching the adipose tissue in which they accumulate. The rate of these compounds increases
44 in the body of the species that live in these environments ~~when we~~with progress in the food chain in which
45 humans are at the top [14-16].

46 As for volatility, it is generally due to the organochlorines' relatively high vapor pressure. This property allows
47 them to travel great distances. Thus, according to some studies [17-19], organochlorine pesticides have been
48 found in environments in which these pesticides have never been used and sometimes even far from the places
49 where they were used. In view of all the above-mentioned, the use of organochlorine pesticides ~~will was~~
50 therefore ~~rbe~~regressed from the 1970s and even several ~~will be~~pesticides containing organochlorines were
51 banned in some countries. But it was until the year 2001 that the first Conference on Persistent Organic
52 Pollutants (POPs) was held. Indeed, in Sweden in 2001, the Stockholm Convention marked the first convention
53 on POPs. This convention has been signed by 151 countries. This high number of signatories of the convention
54 shows its importance. Since then, it was decided to reduce or even to eliminate the production and the
55 exploitation of persistent organic pollutants. Among the 12 organic pollutants covered by this convention, 9
56 represent organochlorine pesticides.

57 The main objective of this study is to perform a QSAR study of organochlorine compounds to determine the
58 descriptors that influence their toxicity.

59 Crum-Brown and Frazer [20] were considered to be the precursors of the QSAR methodology. Indeed, already in
60 1868, they postulated that the biological activity of a molecule is a function of its chemical constitution. In 1893,
61 Richet [21] discovered that the toxicity of organic
62 compounds is inversely proportional to their solubility in water. But the era of QSAR really begins in the 1960s
63 with, on the one hand the publication of Hansch and Fujita [22] and on the other hand, the publication of Free
64 and Wilson [23]. And from then, the number of publications containing the word "QSAR" continues to increase
65 due its ability to predict the properties of chemical compounds.

66

67 **2- MATERIALS AND METHODS**

68 **2.1- Materials**

69 **a- Selection of data set**

70 We investigated about 73 molecules as displayed in Table 2. These molecules were taken from Alan Katritzky et
71 al.'s article [24]. For each molecule, LogLC₅₀ is calculated where LC₅₀ stands for the concentration that causes
72 the death of 50% of the population of the test organism. Besides, the most toxic compound is assumed to display
73 the smallest value of LogLC₅₀. Furthermore, it should be noted that lethal dose (LD) and lethal concentration
74 (LC) are identical. But the difference is related to the mode of penetration of the substance into the body. When
75 the administered substance enters the body by inhalation, the notion of dose is replaced by that of concentration.
76 Thus, the lethal dose 50 becomes the lethal concentration 50 [25]. According to Hodge and Sterner [26]
77 chemicals products can be classified into 6 groups according to their toxicities.

84

Table 1: Class of toxicity according to the scale Hodge and Sterner [27]

Index or class of toxicity	Term commonly used	Toxicological parameter (DL ₅₀)
1	Extremely toxic	DL ₅₀ ≤ 1 mg/kg
2	Highly toxic	1 mg/kg ≤ DL ₅₀ ≤ 50 mg/kg
3	Moderately toxic	50 mg/kg ≤ DL ₅₀ ≤ 500mg/kg
4	Slightly toxic	500 mg/kg ≤ DL ₅₀ ≤ 5000mg/kg
5	almost not toxic	5000 mg/kg ≤ DL ₅₀ ≤ 15000 mg/kg
6	relatively harmless	DL ₅₀ ≥ 15000 mg/kg

92

93 **b- Molecular descriptors**

94 We have calculated several quantum and physicochemical descriptors to carry out the QSAR model.

95
96 > **Quantum descriptors**

97 For quantum descriptors we determined highest occupied molecular orbital energy (E_{HOMO}), lowest unoccupied
98 molecular orbital energy (E_{LUMO}), total energy (E_T), dipole moment (DM), constant volume heat capacity (C_v),
99 entropy (s), thermal energy (E_{th}), highest Mulliken electronic charge (CAE), lowest Mulliken electronic charge
100 (CAF), ionization potential (PI) ; electronic affinity (AE), energy gap between E_{HOMO} and E_{LUMO} (ΔE), absolute
101 electronegativity (χ), Chemical potential (μ), absolute hardness (η), mollesse (ζ) and reactivity index (ω). ~~w~~We
102 also considered the number of chlorine (N_{Cl}) atoms as a descriptor. These descriptors were generated or
103 calculated by Gaussian 03 [27] technique. The calculations were performed, thanks to DFT method with B3LYP
104 as the functional and 6-311++g_(d,p) as basis set. Moreover, they were determined on reference to equations
105 below.

106 $PI = -E_{HOMO}; \quad AE = -E_{LUMO}; \quad \Delta E = E_{LUMO} - E_{HOMO}$
107 $\chi = \frac{E_{LUMO} + E_{HOMO}}{2} = \frac{AE + PI}{2} = -\mu; \quad \eta = \frac{E_{LUMO} - E_{HOMO}}{2} = \frac{PI - AE}{2}; \quad \zeta = \frac{1}{\eta}; \quad \omega = \frac{\mu^2}{2\eta}$

108

109 > **Physicochemical descriptors**

110 For physico-chemical descriptors, we used ChemSketch [28] to determine lipophilicity (LogP), formula weight
111 (M), molar refractivity (Rm), molar volume (Vm), parachlor (Pc), index of refraction (Ir), surface tension (γ),
112 density (d) and polarizability (Pol).

113 **2.2- Methods**

114 **a- Descriptive analysis**

115 XLSTAT [29] software and the principal component analysis (PCA) method were used to realize the matrix of
116 correlation. Principal component analysis (PCA) permits to examine descriptors set and to select the good ones
117 that give the best model at prediction [30]. It allows to identify the descriptors which correlate well with the
118 biological activity Log (LC_{50}).

119

120 **b- Statistical analysis**

121 The establishment of QSAR model consists of making out mathematical relationship between biological activity
122 and chemical descriptors. Thus, QSAR model is considered satisfied when the following conditions are satisfied.

123 The choice of the best statistical model has to satisfy the following criteria that encompass the highest coefficient
124 of determination (R^2), the highest of adjusted determination coefficient ($R_{adjusted}^2$), the highest coefficient of
125 Fischer (F), the highest coefficient of cross validation (R_{CV}^2), the lowest values of Mean Square Error (MSE) and
126 the difference $R^2 - R_{CV}^2 < 0.3$.

127 The calculation of these parameters requires a statistical analysis. The most available methods allowing that
128 calculation are Simple Linear Regression (SLR), Multiple Linear Regression (MLR), neurons networks and
129 Partial Least Squares (PLS). In this article, MLR method of XLSTAT ~~is~~was used to perform the prediction [29].

130 **3- RESULTS AND DISCUSSIONS**

131 **3.1- Matrix of correlation**

132 The principal component analysis permits to perform the matrix of correlation. Any descriptor having a partial
 133 correlation coefficient with the biological activity Log (LC₅₀) less than 0.5 is removed from the descriptors set.
 134 For 2 descriptors having partial correlation coefficients with biological activity greater than 0.5 and whose
 135 partial correlation coefficient between both descriptors is greater than 0.95 then the one with the smallest partial
 136 correlation coefficient with the biological activity is also removed from the descriptors set. And we obtain the
 137 matrix of correlation presented by in Tables 3 and 4. These tables show that the selected descriptors correlate
 138 well with toxicity, because all of correlation's coefficients are higher than 0.5.

140 **Table 3:** Matrix of correlation (Pearson (n)) of quantum descriptors used for model 1

Variables	Log LC ₅₀	E _{LUMO}	S	ZPE	N _{Cl}	ΔE
Log LC ₅₀	1					
E _{LUMO}	0,522	1				
S	-0,848	-0,425	1			
ZPE	0,52	0,668	-0,542	1		
N _{Cl}	-0,569	-0,772	0,536	-0,9	1	
ΔE	0,68	0,336	-0,581	0,182	-0,091	1

141

142 **Table 4 :** Matrix of correlation (Pearson (n)) of Physico-chemical descriptors used for model 2

Variables	Log LC ₅₀	LogP	M	Pc	Ir	γ	D	Pol
Log LC ₅₀	1							
LogP	-0,847	1						
M	-0,871	0,826	1					
Pc	-0,777	0,668	0,779	1

143

144 **3.2- Quantum descriptors model**

145 > Equation of model 1

146 $Log LC_{50} = 3.11 - 12.66 * E_{LUMO} - 0.049 * S - 4.92E-04 * ZPE - 0.51 * NCl + 13.05 * \Delta E$

147 $N = 50 ; R^2 = 0.88 ; R^2_{adjusted} = 0.86 ; R^2_{CV} = 0.86 ; R^2 - R^2_{CV} = 0.02 ;$

148 $MCE = 0.15 ; F = 63.40 ; P_{value} < 0.0001 ; \alpha = 0.05$

149 Here, N is the number of molecule, MCE is Mean Square Error, R^2 is the coefficient of determination,
 150 $R^2_{adjusted}$ is the adjusted coefficient of determination, R^2_{CV} is the coefficient of cross validation and F is the
 151 coefficient of Fischer.

Formatted: Subscript

Formatted: Subscript

Formatted: Subscript

Formatted: Subscript

Formatted: Subscript

Formatted: Subscript

152 Furthermore, the small value of P_{value} means that the selected variables do bring a significant amount of
153 information. The high values of R^2 (0.88) and $R_{adjusted}^2$ (0.86) and the low value of MSE (0.15) including
154 $0.5 < R_{CV}^2 < 0.9$ and $R^2 - R_{CV}^2 < 0.3$ indicate that the proposed model is satisfactory and can predict our
155 biological activity (LC_{50}).

Formatted: Font: 10 pt, Subscript

156 $R_{adjusted}^2 = 0.86$ indicates that the toxicity of 86% of our compounds are described with reliability by the
157 selected descriptors. The high value of the coefficient of Fischer ($F = 63.40$) shows the strong relation which
158 exists between the toxicity and the selected descriptors.

159 We can notice from the analysis of the equation of model 1 that $\text{Log}(LC_{50})$ increases when energy of the lowest
160 unoccupied molecular orbital (E_{LUMO}), the entropy (s), the zero-point energy (ZPE) and the number of chlorine
161 atoms (N_{Cl}) decrease while the gap energy (ΔE) increases. Thus, the toxicity of organochlorine compounds
162 evolves in the same direction as ΔE and in the opposite direction as E_{LUMO} , S , ZPE and N_{Cl} .

Formatted: Subscript

163 The regression line between the experimental and theoretical $\text{Log}LC_{50}$ of the test and the validation set is
164 illustrated in Figure 1. The high value of determination coefficient ($R^2 = 0.88$) and the low value of mean
165 square error $MCE = 0.15$ prove a good similarity between the predicted and experimental values. This good
166 similarity is highlighted also in Figure 2.

Formatted: Font: 10 pt, Subscript

167

168 Figure 1: Regression line of the test and validation sets

169 The regression line of the test set indicates that: $\text{Log}LC_{50\text{theo}} = 0.88 * \text{Log}LC_{50\text{exp}} + 0.18$

170

171

172 Figure 2: Similarity curve of the experimental and predicted values of the quantum descriptors model

173

174 > Contribution of descriptors

175 The contributions of the quantum descriptors in the prediction of the organochlorine
176 molecules toxicity were illustrated by-in the Figure 3. The classification of the contribution of
177 the descriptors in the model is as follows:

$$178 \quad N_{Cl}(-0.74) > S(-0.57) > ZPE(-0.37) > \Delta E(0.35) > ELUMO(-0.19)$$

179 According to the contribution of these descriptors, the number of chlorine molecules (N_{Cl}) is
180 the most important descriptor and lowest unoccupied molecular orbital energy (E_{LUMO}) is the
181 least important descriptor for the prediction of toxicity of organochlorine molecules.

182

183

184 Figure 3: Contribution of descriptors in model 1

185 3.3- Physico-chemical descriptors model

186 > Equation of model 2

$$187 \quad \text{Log LC}_{50} = 9,95 - 0,11 * \text{LogP} - 3,31 * Ir + 0,03 * \gamma - 0,73 * d - 0,22 * pol; \quad N = 50; R^2 = 0,90; MCE = 0,12;$$

$$188 \quad F = 80,29; P_{value} < 0,0001; \alpha = 0,05 \quad R_{adjusted}^2 = 0,89; R_{CV}^2 = 0,89; R^2 - R_{CV}^2 = 0,01$$

189

190 The various calculated parameters prove that the model established with the physicochemical descriptors is
191 predictive and reliable. In this model 89% of our compounds are described with reliability by the selected
192 descriptors. Therefore, this model is assumed-shown to be satisfactory.

193 The toxicity of organochlorine compounds increases when lipophilicity (LogP), density (d), polarisability (pol)
194 and index of refraction decrease and surface tension (γ) increases.

195 The regression line between the experimental and theoretical LogLC_{50} of the test and the validation set is
196 illustrated in Figure 4. Here, the high value of determination coefficient ($R^2 = 0.90$) and the low value of mean

Formatted: Subscript

Formatted: Font: 10 pt, Subscript

197 square error $MCE = 0.12$ prove a good similarity between the predicted and experimental values. This good
 198 similarity is emphasized also into Figure 5.
 199

200
 201 Figure 4: Regression line of the test and validation set
 202 The regression line of the test set indicates that: $LogLC_{50theo} = 0.90 * LogLC_{50exp} + 0.14$
 203

204
 205 Figure 5: Similarity curve of the experimental and predicted values of the physicochemical descriptors model
 206

207 > Contribution of descriptors

208 The contributions of the physicochemical descriptors in the prediction of the organochlorine molecules toxicity
 209 were illustrated ~~by~~ in the Figure 6. The classification of the contribution of the descriptors in the model is as
 210 follows:

211 $Pol(-0.86) > \gamma(0.31) > Ir(-0.20) > d(-0.16) > LogP(-0.10)$

212 According to this classification, polarizability is the most important descriptor and lipophilicity is the least
 213 important descriptor to prediction of toxicity of organochlorine molecules.

214
215 Figure 6: Contribution of descriptors in model 2

216 3.4- Quantum and Physicochemical descriptors model

217 ➤ Equation of model

218 $\text{Log LC}_{50} = 3,72 - 0,14 * \text{LogP} - 0,29 * \text{pol} + 3,17E-02 * \text{S} - 5,70E-04 * \text{ZPE} - 0,36 * \text{NCl}$
 219 $R^2 = 0,94; R^2_{adjusted} = 0,93; R^2_{CV} = 0,93; R^2 - R^2_{CV} = 0,004; MCE = 0,07; F = 134,70; P_{value} < 0,0001;$
 220 $\alpha = 0,05$

221 The greatest values of R^2 ; $R^2_{adjusted}$ and F and the lowest values of MCE and P_{value} shows the strong relation
 222 which exists between the toxicity and the selected descriptors. In this model 93% of our compounds are
 223 described with reliability by the selected descriptors. Then $-R^2_{CV}(= 0,93) > 0,9$ and $R^2 - R^2_{CV}(= 0,004) <$
 224 $0,3$ prove that this model is excellent. This equation shows that LogLC50 of organochlorine molecules increases
 225 when LogP, Pol, ZPE and NCl decrease and S increases.

226 The regression line between the experimental and theoretical LogLC50 of the test and the validation set is
 227 illustrated in Figure 7. The high value of determination coefficient ($R^2 = 0,94$) and the low value of mean
 228 square error $MCE = 0,073$ prove a good similarity between the predicted and experimental values. This good
 229 similarity is demonstrated also through Figure 8.

231 Figure 7: Regression line of the test and validation sets

Formatted: Subscript

232 The regression line of the test set indicates that: $\text{LogLC}_{50\text{theo}} = 0.94 * \text{LogLC}_{50\text{exp}} + 0.09$

233

234

235 Figure 8: Similarity curve of the experimental and predicted values of the quantum and physicochemical
236 descriptors model

237

238 > Contribution of descriptors

239 The contributions of the five descriptors in the prediction of the organochlorine molecules toxicity are illustrated
240 by the Figure 9. The classification of the contribution of the descriptors in the model is as follows:

241 $\text{Pol}(1.14) > \text{Nct}(0.53) > \text{ZPE}(0.43) > \text{S}(0.37) > \text{LogP}(0.13)$

242 According to the contribution of these descriptors, polarizability is the most important descriptor and
243 lipophilicity is the least important descriptor for prediction of toxicity of organochlorine molecules.

244

245 Figure 9: Contribution of descriptors in model

246

247 3.5- Comparison of different models

248 The comparison of the criteria of validation enables us to choose the best model for the toxicity of the
249 organochlorine molecules prediction. These criteria are summarized in the Table 5.

250

251 **Table 5:** Table of comparison of different models

Nature of descriptors	Quantum	Physicochemical	Quantum and Physicochemical
Criteria			
<i>N</i>	50	50	50
<i>R</i>²			
<i>R</i>²_{adjusted}	0.88	0.90	0.94
<i>MCE</i>	0.86	0.89	0.93
<i>F</i>	0.15	0.12	0.07
<i>R</i>²_{CV}	63.40	80.29	134.70
<i>R</i>² - <i>R</i>²_{CV}	0.86	0.89	0.93
<i>P</i> value	0.02	0.01	0.004
<i>α</i>	< 0.0001	< 0.0001	< 0.0001
	0.05	0.05	0.05

252

253 After comparing the validation criteria contained in Table 5, we notice that the best model is that obtained with
 254 the union of both quantum and physicochemical descriptors. This is proven by the highest value of
 255 *R*², *R*²_{adjusted}, *F* and *R*²_{CV} and the lowest values of *MCE* and *R*² - *R*²_{CV}. The values of *R*²_{CV} superior to 0,9 and
 256 *R*² - *R*²_{CV} lower than 0,3 show that the established model
 257 is excellent [31]. Besides, The table below summarizes the different molecules, the experimental values of
 258 toxicity (Log (LC₅₀)_{exp}), the theoretical values of toxicity (Log (LC₅₀)_{theo}) and the ratio (Log (LC₅₀)_{exp} / (Log
 259 (LC₅₀)_{theo}).

260 **Table 6 :** Ratio (Log (LC50))_{exp} / (Log (LC50))_{theo} of mixed model

N°	Compounds	Log(LC ₅₀ exp)	Log(LC ₅₀ theo)	Log(LC ₅₀ exp) / Log(LC ₅₀ theo)
Validation set				
51	1,1-dichloroéthane	3.31	3.225	1.026

70	3,4,5-trichloro-2-methoxyphenol	1.03	0.717	1.437
71	3,4,5-trichlorophenol	0.92	1.073	0.858
72	3,5-dichlorophenol	1.22	1.670	0.730
73	4-chloro-3-methylphenol	1.67	1.884	0.887

261

262 The ratio $(\text{Log (LC50)})_{\text{exp}} / (\text{Log (LC50)})_{\text{theo}}$ varies around 1 for most compounds, which justifies that our model
263 is excellent.

264

265 4- CONCLUSION

266 The organochlorine pesticides constitute a subgroup of the organochlorine compounds. These compounds are
267 well-known for their toxicity. What led us to determine, by QSAR method, the theoretical descriptors which
268 could better explain this toxicity. Firstly, we determined on the one hand the quantum descriptors and on the
269 other hand the physicochemical descriptors. Then, a Principal component analysis enabled us to select the best
270 descriptors. Finally, three QSAR models were established. If the models established with the quantum
271 descriptors only and the physico-chemical descriptors only gave good results with respectively $R^2 =$
272 0.88 ; $R^2_{adjusted} = 0.86$; $R^2_{CV} = 0.86$; $R^2 - R^2_{CV} = 0.02$; $MCE = 0.15$; $F = 63.40$ and $R^2 = 0.90$;
273 $R^2_{adjusted} = 0.89$; $R^2_{CV} = 0.89$; $R^2 - R^2_{CV} = 0.01$; $MCE = 0.12$; $F = 80.29$, the best model was obtained with the
274 combination of the two types of descriptors whose equation and criteria of validation are:

275 $\text{Log LC}_{50} = 3,72 - 0,14 * \text{LogP} - 0,29 * \text{pol} + 3,17\text{E-}02 * \text{S} - 5,70\text{E-}04 * \text{ZPE} - 0,36 * \text{N}_{\text{Cl}}$

276 $R^2 = 0.94$; $R^2_{adjusted} = 0.93$; $R^2_{CV} = 0.94$; $R^2 - R^2_{CV} = 0.004$; $MCE = 0.07$; $F = 134.70$; $P_{value} <$
277 0.0001 ; $\alpha = 0.05$.

278 In perspective, we will determine the descriptors that influence the half-life time and the bioaccumulation factor
279 of organochlorine compounds and then propose less toxic, less bio-accumulative and less persistent
280 organochlorine pesticides.
